

ABSTRACT

SYSTEMS AND METHODS FOR IDENTIFICATION OF LOCATIONS

5

A viewing apparatus provides a user with a view of his or her surroundings and enables the user to select a location from the view of the surroundings for identification. The viewing apparatus transmits location information regarding the selected location to a location identification device. In response to receipt of the location information, the location identification device uses the location information to determine identification information for the location. The location identification device transmits the identification information to the viewing apparatus, which displays the identification information on the view of the surroundings, preferably in association with the selected location. The identification information may include an address, a telephone number, and/or other information.
